### Abstract

This paper reechoes the need to use VOIP-based communication channels in order to reduce the heavy cost burden of communication in Sub Saharan Africa and other developing countries. We focus specifically on the context of the campus environment and implement IP PBX to cut down the cost of placing and receiving voice calls, instant messaging and voice mails with other colleagues connected to an Asterisk server on WIFI-enabled networks. We are motivated by the ease and cost-effectiveness of setting up WIFI-enabled IP network infrastructure which in recent times could be extended to allow inter-institutional linkage to allow collaboration and research.

### 1. Introduction

Countries situated in Sub Saharan Africa and other developing countries in general, have traditionally been characterised as having poor physical infrastructure, such as roads and telecommunication. As a consequence, most countries in these regions have closed the chapter on obtaining telephone lines and fully embraced mobile communication. The existing evidence with regard to mobile communication show benefits in various facets of life such as in agriculture where improved market efficiency and reduced consumer prices for certain commodities has been reported [1], in health and trauma cases such as post-rape service delivery [2], and in the banking sector where mobile banking has brought on board the unbanked [3].

Although many benefits are reported of mobile communication for development, most users in Sub Saharan Africa continue to perceive high costs attached to the mobile internet communication emanating from the mobile data prices. As long as users continue to associate the internet with higher data

prices, there will be no full maturity usage of the internet in Sub Saharan Africa, and more so users in low resource settings. For example, a survey of mobile phone usage in five African countries (Kenya, Uganda, South Africa, Ghana, and Nigeria) has found that Internet browsing via phones now stands at 40 per cent across these countries, with 51% of respondents in Ghana and 47% in Nigeria reporting that they use their phones to access the internet. South Africa lags behind at 40%, and Kenya (34%) and Uganda (29%) are slowest on the uptake (<http://www.itnewsafrika.com/>). Consumers in South Africa, one of the countries which have a higher increased uptake of smartphones, are at the forefront in voicing their discomfort with the high data prices via #Datamustfall [4]. Comparatively, South Africa's data prices are much higher than those in other countries on the continent and in the world. This is concerning because according to [5], unless we tackle the issue of unaffordable internet, we're just going to go on entrenching and worsening the existing divides and inequalities in our country'. Consumers in the low remote areas of Sub Saharan Africa, who are unable to afford high costs of data, will be worse off in this digital age. This problem is more severe for students who are in areas with shortages of qualified teachers and traditional

educational resources such as textbooks [6]. In some of these settings, studies have confirmed that access to the internet does contribute to student learning. For example, [7] reports that students spent significantly more time using the university's learning management system when classes were in session.

[8] Found that sixty percent of medical students in Pakistan used the internet sites to access subjects on medical topics. They report less utilization of internet however which was due to slow speed of data transfer. [9] Shows how effective mobile internet is in a learning system in secondary and higher secondary level students.

The context of this study is therefore in higher education institutions where students continue to face challenges of access to the internet and learning material. Students have mobile phones which can aid their learning for example having a chat discussion about a specific topic, but this is hampered by mobile data costs. When students attempt to make communication with fellow students on matters related to academia, they incur high costs because even though they reside in the same campus, the call signaling and voice traffic are always routed to the core network, which incurs extra telephony cost [10]. This study proposes a test-base using Zoiper (SIP clients) and Asterisk server Private Branch Exchange (PBX) for an intranet VOIP application. The Zoiper and Asterisk intranet VOIP implementation allows free communication without the need for telecommunication provider charges be it call or data rates [11]. Zoiper (SIP client) is based on a custom configured PBX using the Asterisk server to facilitate student communications across a multiple university campus setting in developing countries. [12] defined PBX as a telephone system that switches calls between users within a small area, such as a hotel, an office building, or a hospital. Most higher institutions of learning have installed wired and wireless intranet (e.g. LAN) making it possible for them to implement and manage their own PBX. The campus PBX using Zoiper and Asterisk is therefore intended to tap into these intranet services to allow students easier and free communication, specifically make phone calls and have instant messaging services. Students can make phone calls and have instant messaging services. Although PBX is an old technology, it has not yet been fully utilized in the education context of Sub Saharan Africa and this study considers PBX to be a paramount solutions for the challenges of students in developing countries, and as [13] notes, PBX should be considered as part of a nation's critical infrastructure, along with the public telephone network.

The rest of the paper is structured as follows: related works on PBX and its use in developing countries is covered in Section II. Section III outlines the research methodology. Section IV presents the findings. Section V discusses the findings and section VI concludes the paper.

## 2. Related work

### 2.1. Mobile data costs in developing countries

For internet utilization to spread and become mature in Sub Saharan Africa, mobile data prices have to be perceived affordable or free for the majority of people, both for the urban and rural communities. According to Tariffic (FinTech.com), some countries in Africa, such as South Africa, face higher data costs when compared to BRICS-member countries Brazil, Russia, India and China, and that data prices for South Africa were on average 134% more expensive than the cheapest prices in the group". South African consumers have publicly made the awareness of high data costs and have called for its reduction through various channels such as the #DataMustFall [4] initiative [14] [4].

As more countries start to adopt smart phones and the need for mobile data increases, cost will remain a problem. According to the latest study by [15] the common use of mobile phones in Africa includes sending text messages, taking pictures or video, and mobile banking. Other reasons include getting political news, accessing a social networking site, getting health and consumer information and looking for a job. Even in countries with low data costs in Sub Saharan Africa such as Tanzania, there remains low mobile internet usage. According to [16], one of the principal reasons, specifically amongst users situated in low resource settings (rural areas, example farmers) is because "of price charged per MB when downloading info/docs or browsing websites e.g. Google". These findings show the significant importance of finding solutions to address data costs in developing countries where, average monthly fixed broadband prices are three times higher than in developed countries and mobile broadband prices are twice as expensive as in developed countries [17]. To attain internet usage maturity, there is need to decrease the prices because the decrease in mobile-broadband prices goes hand in hand with an increase in the intensity of use [17].

### 2.2. PBX application use in the context of higher institutions

Although the use of the internet in developing countries is low, this could potentially change if internet use is perceived affordable and if possible free, especially in areas perceived to be either critical for operations such as in health or important for supplementing existing educational material. Those in the education sector have since identified the importance of ICT and the internet in particular in learning for students who reside in areas where access to learning material and teachers is a challenge. Most learning institutions in developing countries now have access to Internet but its use for most students remains a challenge due to the high cost. As a consequence, students remain at a disadvantage when comparing them to students in the developed economies.

Several solutions have been proposed to address student access to the internet within their limited locale such as a campus, but few focus on the context of Sub Saharan Africa. One example is the VillageCell solution by [18] of multiple base stations which are connected through the local wireless network, and calls are routed via private branch exchange (PBX) servers implemented in an open source framework (Asterisk). VillageCell in Africa allows free calls within the local network and standard connections to outside callers using the satellite link. It also uses free, open source solutions and off-the-shelf hardware, and hence the total deployment cost is minimal and the solution is scalable. Examples that feature specifically in the context of education campus include the works of [19] who designed and implemented an Asterisk server to serve as the local exchange for placing voice and video calls within a private WIFI cloud and legacy networks (Public Switched Telephony Network). Their model which is accessible within the area of a university campus, allows only those mobile phones and PCs to connect to the Asterisk server which are registered with the wireless network. [20] Developed a VOIP based Asterisk PBX on Ubuntu 11.10 which allow unlimited free calls with the help of IP phone or traditional phone within a LAN/WAN without internet connection. For wireless communication, the authors whose study was situated in Asian context where there is limited bandwidth, extended VOIP based PBX to WIFI technology. [21] Present a VOIP based solution designed for the use over a campus environment whose operating costs of phone systems take a large part of the budget. Their proposed solution is designed to carry all telephony signals by offering a new communication tool in which data packet streams are transmitted over IP. Like a standard SIP server, the solution is an IP software which can simultaneously act as a phone gateway for the phone system.

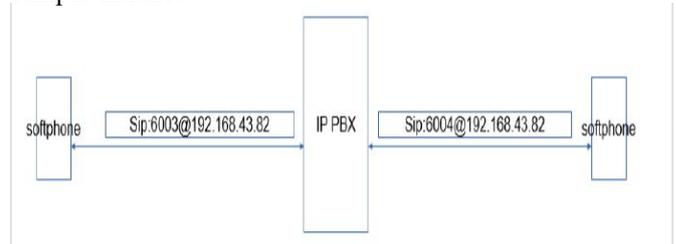

### 3. Methodology

VOIP technique is gradually becoming the most common communication system as a result of its benefits over the Public Switched Telephone Network (PSTN). This communication technique is popular to many who are not new to using softphone application such as Skype, WhatsApp, Imo, Facebook and the like. VOIP offers less expenditure as well superior flexibility, management and support compared to the PSTN [22]. Hence, for this study, VOIP implementation using campus IP intranet was used to explore the most economical means of communication and exchanging information. Not only can campus VOIP deliver voice services, but stakeholders could appreciate multimedia sessions such as video conferencing, telepresence, instant messaging and fax data over intranet using Internet Protocol at no usage cost. In this study we propose a test-based WIFI-enabled campus intranet with VOIP integration using Zoiper softphone (SIP clients) and Asterisk server as the Internet Protocol (IP)-PBX. The PBX is a private telephone exchange allowing multiple telephones to be connected together for communication [19].

### 3.1. System Architecture

Three VOIP software packages, Asterisk, Trixbox, and PBX in a Flash (PBXiF), were selected for testing as a replacement for the old PBX system. These selections were made based on three criteria: 1) cost of acquisition and support, 2) availability of forums or technical support groups, and 3) compatibility with industry standard hardware platforms [23]. The most known telephone software for processing calls and providing a powerful control over call activity is Asterisk [24]; therefore, this study used the Asterisk IP PBX, a system that enables call routing and other VOIP functions for the VOIP phones [24]. PBX is situated on the network Infrastructure layer which is responsible for communications where the Delivering information and transferring Voice are based on specific protocols, such as session initiation protocol (SIP) and real time protocol (RTP) [25].

The SIP client softphone (Zoiper) was opted for the campus intranet VOIP solution as SIP is one of the most widely used voice signalling protocols developed by the Internet Engineering Task Force –IETF [26]. Furthermore, [22] mentions SIP forms the major basis as the standard signaling for IP networks to enable VOIP. Thus, PBX and network systems that do not support SIP would be replaced with SIP enabled PBX and network systems that are packet switched and IP enabled. Figure 1 shows the IP PBX and its connections to the various client softphones; the sip:6003@192.168.43.82 and sip:6004@192.168.43.82 SIP addresses are used by the IP PBX to identify and communicate with the various SIP-client softphones on the campus intranet.

**Figure 1.** The IP PBX SIP registration Diagram

With this setup, the operational cost is significantly reduced, since the voice communication infrastructure becomes part of the campus intranet, instead of being provided by the Telephone Company. Another important consideration, is that we use an open source PBX called Asterisk to develop this layer. Furthermore, to check the user's connection (in telephony this requirement is called presence), we set up an Openfire server connected to the PBX to manage presence feature. We used Asterisk as it is an open source PBX and it supports all the security techniques. The Asterisk PBX software was loaded on two Dell Desktop machines [25].

### 3.2. Implementation

system to uniquely identify each user and are referenced by the dial plan to route calls to the right destinations. **Figure 6** shows the configuration for the chan\_sip channel driver.

```

context=gasfella
disallow=all
allow=gsn,opus
```

**Figure 6.** Chan\_sip Channel Driver Configuration

#### 4. Findings

With regards to testing the Asterisk PBX call process (refer to **Figure 7**), the SIP clients, being soft phones, register once with the Asterisk PBX server, and when they wish to make a call, they ask the PBX to establish the connection. When the connection is established, a channel brings the call to the Asterisk PBX, converting the analogue signal to a digital format by means of codecs (using the pulse code modulation technique (PCM)) and translated over the network. Each call is received and placed on a separate channel.

**Figure 7.** The Asterisk PBX call process.

The Asterisk PBX has a directory of all users and their corresponding SIP address and thus is able to connect a call to the desired destination. For example, **Figure 8** shows one of the successful registrations of SIP clients 6003 and 6004 on the PBX system for call process.

```
Asterisk Ready.
- Registered SIP '6003' at 192.168.43.1:34219
  > Saved useragent "Zoiper r33488" for peer 6003

## 5. Discussion

Most developing countries and more specifically campuses that are in remote areas tend to face challenges of communication, despite having access to a mobile phone. Usually, those who want to access the Internet are faced with the data cost problems which deter them from communication and ultimately internet use. This is a challenge more experienced by students in rural settings whose need for the internet resources is important to supplement their scarce resources such as books and adequate teachers. In this study, we address the problem of data cost by taking advantage of and implementing the IP PBX, which then addresses the communication needs of the already over-burdened student. Registered clients within the proximal range of the campus WIFI are able to communicate effectively with each other through calls, voice mails and instant messaging without having to incur any cost. Beyond the campus WIFI range, it is still possible to connect to the server through the internet using SIP-trunks in order to communicate with those who are also connected to the server either through the WIFI or the internet. Hence, some cost is incurred only in the case where the student is either beyond the campus WIFI range or is communicating with a person not on the WIFI. The study therefore confirms earlier works on the economics of IP-PBX which makes Voice over IP (VOIP) a cost-effective alternative to the legacy PBX or key system [27].

## 6. Conclusion

The purpose of this study was to address the challenges experienced in developing countries around data costs which in turn hamper communication. Taking a higher education context as the setting for the study, we propose a test-base using Zoiper (SIP clients) and Asterisk server Private Branch Exchange (PBX) for an intranet VOIP application as a way of addressing the challenges students experience at higher institutions. The findings show that such a solution is effective and economical for institutions in developing countries. This study therefore is a contribution towards the ICT4D agenda of having existing or innovative ICTs address challenges experienced by people in developing country context. There is abundant room for further progress by presenting numerical data on the mobile data costs and the savings expected from the suggested solution in order to evaluate the effectiveness of the suggested solution in real scenarios. Also, further research is required to establish metrics on the scale of deployment focusing on number of users, concurrent call sessions and statistical volume of traffic analysis needed to be supported.
