WG-8: A Lightweight Stream Cipher for **Resource-Constrained Smart Devices**

Xinxin Fan^{*}, Kalikinkar Mandal and Guang Gong

Department of Electrical and Computer Engineering University of Waterloo Waterloo, Ontario, N2L 3G1, CANADA

Abstract

Lightweight cryptographic primitives are essential for securing pervasive embedded devices like RFID tags, smart cards, and wireless sensor nodes. In this paper, we present a lightweight stream cipher WG-8, which is tailored from the well-known Welch-Gong (WG) stream cipher family, for resource-constrained devices. WG-8 inherits the good randomness and cryptographic properties of the WG stream cipher family and is resistant to the most common attacks against stream ciphers. The software implementations of the WG-8 stream cipher on two popular low-power microcontrollers as well as the extensive comparison with other lightweight cryptography implementations highlight that in the context of securing lightweight embedded applications WG-8 has favorable performance and low energy consumption.

Keywords: Lightweight stream cipher, resource-constrained smart device, cryptanalysis, efficient implementation.

1. Introduction

The Internet of Things (IoT) is an emerging computing and communication paradigm in which smart devices (e.g., RFID tags, smart cards, wireless sensor nodes, etc.) are linked through both wired and wireless networks to the Internet. Those smart devices interact and cooperate with each other to conduct complicated tasks such as sensing the environment, interpreting the data, and responding to events. While the IoT provides new and exciting experience for end users, it also opens up new avenues to hackers and organized crime. Recent attacks to a wide range of smart devices [14, 41] have emphasized that without adequate security the IoT will only become pervasive nightmare.

The challenges for deploying security solutions for smart devices are threefold: 1) The overhead (i.e., the gate count in hardware or the memory footprint in software) of security solutions should be minimal due to the low-cost nature of smart devices; 2) The power consumption of security solutions should be minimal due to the low-power characteristic of smart devices; and 3) The performance of security solutions should be reasonable to support applications and end-user requirements. To address the aforementioned challenges for securing smart devices, a new research direction called *lightweight cryptography* has been established which focuses on designing novel cryptographic algorithms and protocols tailored for implementation in resource-constrained environments.

A host of lightweight symmetric ciphers that particularly target for resource-constrained smart devices have been proposed in the past few years. Early work focuses on optimizing hardware implementations of standardized block ciphers such as AES [18], IDEA [26] and XTEA [23]. Later on, researchers have shown how to modify a classical block cipher like DES [25] for lightweight applications. Recent proposals deal with new low-cost designs, including lightweight block ciphers

PRESENT [5], KATAN/KTANTAN [6], PRINTcipher [24], LED [21], and Piccolo [38], lightweight stream ciphers Grain [22], Trivium [7], and MICKEY [3], as well as a lightweight hybrid cipher Hummingbird/Hummingbird-2 [16, 17]. A good research survey about recently published lightweight cryptographic implementations can be found in [15].

In this paper we present the stream cipher WG-8, which is a lightweight variant of the well-known WG stream cipher family [31] as submitted to the eSTREAM project. WG-8 inherits good randomness properties of the WG stream cipher family such as period, balance, ideal two-level autocorrelation, ideal tuple distribution, and exact linear complexity. Moreover, WG-8 is able to resist the most common attacks against stream ciphers including algebraic attack, correlation attack, differential attack, cube attack, distinguish attack, discrete fourier transform attack, and time-memory-data tradeoff attack, thereby providing adequate security for lightweight embedded applications.

We also propose several techniques for efficient implementation of the stream cipher WG-8 on two lowpower microcontrollers, including an 8-bit microcontroller ATmega128L from Atmel and a 16-bit microcontroller MSP430 from Texas Instruments. Our experimental results show that WG-8 can achieve high throughput of 185.5 Kbits/s and 95.9 Kbits/s on the above two microcontrollers with energy efficiency of 458 nJ/bit and 125 nJ/bit, respectively. When compared to other lightweight cryptography implementations in the literature, the throughput of the WG-8 is about $2 \sim 15$ times higher and the energy consumption is around $2 \sim 220$ times smaller than those of most previous ciphers.

The remainder of this paper is organized as follows. Section 2 gives a description of the lightweight stream cipher WG-8. Subsequently, in Section 3 we analyze the security of the WG-8 against the most common attacks to stream ciphers. Section 4 describes efficient techniques for implementing the WG-8 stream cipher on low-power microcontrollers and reports our experimental results and comparisons with previous work. In Section 5, we briefly review recent progress on efficient hardware implementation of the WG-8 stream cipher. Finally, Section 6 concludes this contribution.

2. The Lightweight Stream Cipher WG-8

2.1. Preliminaries

We define the terms and notations that will be used to describe the lightweight stream cipher WG-8 and its architecture as well as to characterize its randomness and cryptographic properties.

- $\mathbb{F}_2 = \{0, 1\}$, the Galois field with two elements 0 and 1.
- p(x) = x⁸ + x⁴ + x³ + x² + 1, a primitive polynomial of degree 8 over 𝔽₂.
- \mathbb{F}_{2^8} , the extension field of \mathbb{F}_2 defined by the primitive polynomial p(x) with 2^8 elements. Each element in \mathbb{F}_{2^8} is represented as an 8-bit binary vector. Let ω be a primitive element of \mathbb{F}_{2^8} such that $p(\omega) = 0$.
- $\operatorname{Tr}(x) = x + x^2 + x^{2^2} + \dots + x^{2^7}$, the trace function from $\mathbb{F}_{2^8} \mapsto \mathbb{F}_2$.
- l(x) = x²⁰ + x⁹ + x⁸ + x⁷ + x⁴ + x³ + x² + x + ω, the feedback polynomial of LFSR (which is also a primitive polynomial over F₂₈).
- $q(x) = x + x^{2^3+1} + x^{2^6+2^3+1} + x^{2^6-2^3+1} + x^{2^6+2^3-1}$, a permutation polynomial over \mathbb{F}_{2^8} .
- WGP-8(x^d) = q(x^d + 1) + 1, the WG-8 permutation with decimation d from F_{2⁸} → F_{2⁸}, where d is coprime to 2⁸ 1.
- WGT-8 $(x^d) = \text{Tr}(\text{WGP-8}(x^d)) = \text{Tr}(x^9 + x^{37} + x^{53} + x^{63} + x^{127})$, the WG-8 transformation with decimation d from $\mathbb{F}_{2^8} \to \mathbb{F}_2$, where d is coprime to $2^8 1$.
- Polynomial basis (PB) of F₂₈: A polynomial basis of F₂₈ over F₂ is a basis of the form {1, ω, ω², · · · , ω⁷}.
- Normal basis (NB) of F₂^s: A normal basis of F₂^s over F₂ is a basis of the form {θ, θ², · · · , θ^{2⁷}}, where θ = ω⁵ (i.e., a normal element) is used in this work.
- Autocorrelation: The autocorrelation of a binary sequence with period T is defined as the difference between the agreements and disagreements when the symbol 0 maps to 1 and 1 maps to -1. If all

the out-of-phase autocorrelation is equal to -1, then the sequence is said to have *ideal two-level autocorrelation*.

- Linear span (LS): The linear span or linear complexity of a binary sequence is defined as the length of the smallest linear feedback shift register (LFSR) which generates the entire binary sequence.
- Nonlinearity: The nonlinearity of a function f is defined as the minimum distance from f to any affine function with the same number of variables.
- Algebraic immunity (AI): The algebraic immunity of a function f is defined as the minimum degree of an annihilator Boolean function g such that gis equivalent to either f or the complement of f(i.e., fg = 0 or (f + 1)g = 0). In the ideal case, the algebraic immunity of a function f is equal to the degree of f, thus making it immune to algebraic attacks.
- \oplus , the bitwise addition operator (i.e., XOR).
- \otimes , the multiplication operator over \mathbb{F}_{2^8} .

2.2. The Description of the Stream Cipher WG-8

WG-8 is a lightweight variant of the well-known Welch-Gong (WG) stream cipher family with 80-bit secret key and 80-bit initial vector (IV), which can be regarded as a nonlinear filter generator over finite field \mathbb{F}_{2^8} . The stream cipher WG-8 consists of a 20-stage LFSR with the feedback polynomial l(x) followed by a WG-8 transformation module with decimation d = 19, and operates in two phases, namely an initialization phase and a running phase.

Initialization Phase. The key/IV initialization phase of the stream cipher WG-8 is shown in Figure 1.

Figure 1. The Initialization Phase of the Stream Cipher WG-8 $\,$

Let the 80-bit secret key be $K = (K_{79}, \ldots, K_0)_2$, the 80-bit IV be $IV = (IV_{79}, \ldots, IV_0)_2$, and the internal state of the LFSR be $S_0, \ldots, S_{19} \in \mathbb{F}_{2^8}$, where $S_i = (S_{i,7}, \ldots, S_{i,0})_2$ for $i = 0, \ldots, 19$. The key and IV initialization process is conducted as follows: $S_{2i} = (K_{8i+3}, \ldots, K_{8i}, IV_{8i+3}, \ldots, IV_{8i})_2$ and $S_{2i+1} =$ $(K_{8i+7}, \ldots, K_{8i+4}, IV_{8i+7}, \ldots, IV_{8i+4})_2$ for $i = 0, \ldots, 9$.

Once the LFSR is loaded with the key and IV, the apparatus runs for 40 clock cycles. During each clock cycle, the 8-bit internal state S_{19} passes through the nonlinear WG-8 permutation with decimation d = 19 (i.e., the WGP-8(x^{19}) module) and the output is used as the feedback to update the internal state of the LFSR. The LFSR update follows the recursive relation:

$$S_{k+20} = (\omega \otimes S_k) \oplus S_{k+1} \oplus S_{k+2} \oplus S_{k+3} \oplus S_{k+4} \oplus$$

$$S_{k+7} \oplus S_{k+8} \oplus S_{k+9} \oplus \mathsf{WGP-8}(S_{k+19}^{19}), \quad 0 \le k < 40.$$

After the key/IV initialization phase, the stream cipher WG-8 goes into the running phase and 1-bit keystream is generated after each clock cycle.

Running Phase. The running phase of the stream cipher WG-8 is illustrated in Figure 2. During the running phase, the 8-bit internal state S_{19} passes through the nonlinear WG-8 transformation with decimation d = 19 (i.e., the WGT-8(x^{19}) module) and the output is the keystream. Note that the only feedback in the running phase is within the LFSR and the recursive relation for updating the LFSR is given below:

$$S_{k+20} = (\omega \otimes S_k) \oplus S_{k+1} \oplus S_{k+2} \oplus S_{k+3} \oplus S_{k+4} \oplus S_{k+7} \oplus S_{k+8} \oplus S_{k+9}, \quad k \ge 40.$$

The WG-8 transformation module WGT-8 (x^{19}) comprises of two sub-modules: a WG-8 permutation module WGP-8 (x^{19}) followed by a trace computation module Tr (\cdot) . While the WGP-8 (x^{19}) module permutes elements over \mathbb{F}_{2^8} , the Tr (\cdot) module compresses an 8-bit input to 1-bit keystream.

2.3. Randomness Properties of the WG-8 Keystream

The keystream generated by the stream cipher WG-8 has the following desired randomness properties [8]:

Figure 2. The Running Phase of the Stream Cipher WG-8

- 1. The keystream has a period of $2^{160} 1$.
- 2. The keystream is balanced, i.e., the number of 0's is only one less than the number of 1's in one period of the keystream.
- 3. The keystream is an ideal two-level autocorrelation sequence.
- 4. The keystream has an ideal t-tuple $(1 \le t \le 20)$ distribution, i.e., every possible output t-tuple is equally likely to occur in one period of the keystream.
- 5. The linear span of the keystream can be determined exactly, which is $2^{33.32}$.

3. Cryptanalysis of the Stream Cipher WG-8

In this section, we analyze the security of the stream cipher WG-8 under the context of lightweight embedded applications. Note that for security applications (e.g., encryption, authentication, etc.) with smart devices the communication sessions are typically short (i.e., a few rounds among communication entities) and the length of transmitted messages is generally quite limited (i.e., tens to hundreds of bytes) in each communication session, due to the constrained power and communication bandwidth of smart devices. As a result, it is extremely difficult, if not impossible, for an adversary collecting consecutive and long enough keystream to conduct cryptanalysis in practice for a well-designed lightweight stream cipher. The design of the stream cipher WG-8 keeps in mind the real-world embedded security applications and the appropriate selection of system parameters enables WG-8 to thwart various cryptanalytic attacks in practice, as detailed in the following subsections.

3.1. Algebraic Attack

The algebraic attack is a powerful attack against LFSR based filtering sequence generators [11]. The goal of the algebraic attack is to form a lower degree multivariate equation by multiplying the filtering function by a low-degree multivariate polynomial. This gives an overdefined system of nonlinear equations for sufficiently many keystreams, which can be solved to recover the internal state of the LFSR. The algebraic immunity of the WGT-8 (x^{19}) is equal to 4. According to the algebraic attack, the time complexity and the data complexity for recovering the internal state of the LFSR are about $\frac{7}{64} \cdot {\binom{160}{4}}^{\log_2 7} = 2^{66.0037}$ and ${\binom{160}{4}} = 2^{24.65}$, respectively. For applying the fast algebraic attacks [10] to the stream cipher WG-8, one needs to respectively find two multivariate polynomials g and h of degree e and d (e < d) such that $f \cdot g = h$. For the WGT-8 (x^{19}) and e = 1, there does not exist a multivariate polynomial hin 8 variables with degree less than 7. Hence, in order to launch the fast algebraic attack one needs to obtain more keystream bits with a higher complexity. For lightweight embedded applications, it is hard for an attacker to obtain about $2^{24.65}$ keystream bits. Even if the attacker can get those many bits for a fixed key and IV, he needs to perform the operations with the time complexity $2^{66.0037}$, which completely defeats this attack.

3.2. Correlation Attack

In the correlation attack, the objective of an attacker is either to find the correlation between a keystream and an output sequence of an LFSR or to find the correlation among the keystreams [9, 28, 39]. The stream cipher WG-8 is secure against the correlation among the keystreams as it produces keystreams with 2-level autocorrelation. We now consider the fast correlation attack in which the keystream of the stream cipher is considered as a distorted version of the LFSR output. In the fast correlation attack, the linear approximation of WGT-8 (x^{19}) can be used to derive a generator matrix of a linear code that can be decoded by a maximum likelihood decoding (MLD) algorithm. Letting f(x) be a linear function in 8 variables, we have $\Pr(WGT-8(x^{19})(x) =$ $f(x) = \frac{(2^8 - 108)}{2^8} = 0.578125$. Applying the results of [9] for t = 3, the amount of keystream (denoted by

N) required for the attack to be successful is given by $N \approx (k \cdot 12 \cdot \ln 2)^{\frac{1}{3}} \cdot \epsilon^{-2} \cdot 2^{\frac{160-k}{3}}$ and the decoding complexity is given by $C_{dec} = 2^k \cdot k \cdot \frac{2\ln 2}{(2\epsilon)^6}$, where $\epsilon =$ $(\Pr(WGT-8(x^{19}) = f(x)) - 0.5) = 0.078125$ and k is the number of LFSR internal state bits recovered. If we choose a small value of k (e.g., k = 7), the number of bits required to launch the attack is about $2^{60.31}$, which is not possible in practice. Similarly, if we choose a large value of k (e.g., k = 80), the number of bits required to mount the attack is about $2^{37.15}$. However, the decoding complexity of the attack is approximately $2^{102.68}$, which is worse than the exhaustive search. Hence, the stream cipher WG-8 is secure against the fast correlation attack.

3.3. Differential Attack

The initialization phase in the first design of the WG stream cipher was vulnerable to the chosen IV attack [43], where an attacker can distinguish several output bits by building a distinguisher based on the differential cryptanalysis. This weakness has been fixed in the later design by placing the WG permutation module at the last position of the LFSR [31]. For the proposed stream cipher WG-8, the differential distribution of the WGP-8(x^{19}) is 8-uniform, which provides a maximum 2^{-5} possibility for differential characteristic. During the initialization phase the WGP-8(x^{19}) is applied for 40 times. Thus, after the initialization phase, it would be quite hard for an attacker to distinguish the output keystream since the differentials become complex and contain most key/IV bits.

3.4. Cube Attack

Cube attack [13] is a generic key-recovery attack that can be applied to any cryptosystem, provided that the attacker can obtain a bit of information that can be represented by a low-degree decomposition multivariate polynomial in Algebraic Normal Form (ANF) of the secret and public variables of the target cryptosystem. Note that the nonlinearity of WGP-8(x^{19}) is 92 and the algebraic degrees of the component functions of WGP-8(x^{19}) are 7. Moreover, the ANF representations of 8 component functions contain 133, 113, 146, 124, 137, 109, 122, and 120 terms, respectively, and only the ANF of the second component contains 7 linear terms and other terms are of degree greater than or equal to 2. In the WG-8 stream cipher, after 40 rounds of the initialization phase, the degree of the output polynomial can be very high. As a result, it would be hard for an attacker to collect low-degree relations among the secret key bits.

3.5. Distinguishing Attack

Recently, a distinguishing attack has been proposed against the stream cipher WG-7 [32]. Due to the small number of tap positions in the LFSR of the WG-7, the characteristic polynomial of the LFSR allows an attacker to build a distinguisher for distinguishing a keystream generated by WG-7 from a truly random keystream. For the WG-8 cipher, the characteristic polynomial of the LFSR consists of 8 tap positions and a similar distinguisher as in [32] can be built as

$$\begin{split} F(S_i,...,S_{i+4},S_{i+7},...,S_{i+9}) &= \mathsf{WGT-8}(\omega \otimes S_i \oplus S_{i+1} \oplus S_{i+2} \oplus S_{i+3} \oplus S_{i+4} \oplus S_{i+7} \oplus S_{i+8} \oplus S_{i+9}) \oplus \\ \mathsf{WGT-8}(S_i) \oplus \mathsf{WGT-8}(S_{i+1}) \oplus \mathsf{WGT-8}(S_{i+2}) \oplus \\ \mathsf{WGT-8}(S_{i+3}) \oplus \mathsf{WGT-8}(S_{i+4}) \oplus \mathsf{WGT-8}(S_{i+7}) \oplus \\ \mathsf{WGT-8}(S_{i+8}) \oplus \mathsf{WGT-8}(S_{i+9}), \end{split}$$

which is a Boolean function in 64 variables. For the distinguisher F, the probability $\Pr(F(x) = 0) = \frac{1}{2} \pm \epsilon$, where $x = (a_0, ..., a_7), a_i \in \mathbb{F}_{2^8}$. Note that the value of ϵ will be quite small due to a huge number of variables in the distinguisher, which requires an attacker to obtain more keystream bits for distinguishing the keystream. However, the computation of the exact value of ϵ is infeasible in this case because the number of possible values of x is 2^{64} . Hence the WG-8 stream cipher is resistant to the distinguishing attack. Note that this type of distinguishing attacks can also be extended to the case in which a distinguisher can be built using a linear relation of a remote term of the LFSR, say S_{τ} for not large τ , and the sequences addressed in a subset of tap positions of the LFSR, denoted by $I = \{i_1, \dots, i_t\} \subset$ $\{0, 1, \dots, 19\}$. In other words, a distinguisher could be built using the linear relation $S_{\tau} = S_{i_1} + \cdots + S_{i_t}$. Since this property is controlled by the characteristic polynomial of the LFSR, it can be easily teared done by a proper selection of the characteristic polynomial of the LFSR. For our selection of the characteristic

polynomial l(x), there is no remote term S_{τ} for $20 \leq \tau \leq 2^{34}$ for which the size of set I is less than 5. Thus, the WG-8 stream cipher is also resistant to this general distinguishing attack.

3.6. Discrete Fourier Transform Attack

The Discrete Fourier Transform (DFT) attack is a new type of attack to recover the internal state of a filtering generator, which was first proposed by Rønjom and Helleseth in [36] and extended to attacking filtering generators over \mathbb{F}_{2^n} by Gong *et al.* in [20]. For mounting the DFT attack against the WG-8 stream cipher, an attacker needs to obtain $2^{33.32}$ (i.e., the linear complexity) consecutive keystream bits. Hence, the online complexity of this attack for recovering the internal state is $2^{33.32}$, after an offline computation with complexity $2^{48.49}$. For typical lightweight embedded applications like RFID systems, a reader and a tag only exchange 32-bit random numbers in each communication session. Hence, an attacker can never obtain $2^{33.32}$ consecutive keystream bits.

3.7. Time-Memory-Data Tradeoff Attack

The Time-Memory-Data (TMD) tradeoff attack [4] is a generic cryptanalytic attack that is applicable to any stream cipher, especially those with low sampling resistance. The complexity of the TMD tradeoff attack is $O(2^{\frac{n}{2}})$, where *n* is the size of the internal state. For the WG-8 stream cipher, the size of the internal state is 160bit and thus the complexity of launching a TMD attack is at least 2^{80} . Moreover, the sampling resistance of the WG-8 stream cipher is high due to the usage of the WGT- $8(x^{19})$ as the filtering function. The ANF representation of the WGT- $8(x^{19})$ contains 109 terms, among which only four terms are linear and other terms have degree greater than 2 and less than 8. Hence, only by fixing 7 out of 8 variables can one obtain a linear equation.

3.8. Related-key Attack

A related-key attack is a cryptanalytic attack that can also be applied to a stream cipher and allows to launch a key-recovery attack. In [12], Ding *et al.* proposed a key-recovery attack in the related key settings on WG-8 stream cipher by exploiting the slide property of WG-8 stream cipher. The key-recovery attack has a time complexity of $2^{53.32}$ and needs 2^{52} chosen IVs. From the DFT attack on WG-8 stream cipher, it can be observed that the DFT attack has an online time complexity of $2^{33.32}$ and data complexity of $2^{33.32}$, which are much lower than the complexities of Ding *et al.*'s key-recovery attack. We believe that the key-recovery attack by Ding *et al.* is not a real threat on our WG-8 stream cipher.

3.9. Mihaljević et al.'s Attack

In [30], Mihaljević *et al.* proposed an internal state recovery attack on Grain-v1 by exploiting the normality of the filtering function of Grain-v1. Their cryptanalysis exploits three facts: a) the bias towards a subset of the internal states; b) recovering some partial key bits; and c) adaptation of the TMD tradeoff approach to use the bias of the internal state. We note that the bias of the internal states is detected by using the normality of the filtering function. Since an LFSR that generates an *m*-sequence is used to update the internal state of WG-8 stream cipher, no such bias on the internal state exists in the internal state. Moreover, the normality of WGT-8(x^{19}) is 3. Therefore, Mihaljević *et al.*'s attack cannot be applied to the WG-8 stream cipher.

4. Efficient Software Implementation of the Stream Cipher WG-8

In this section, we address efficient software implementation of the WG-8 cipher on low-power microcontrollers. For each platform we provide three implementation variants that deal with trade-offs among speed, code size, and energy consumption.

4.1. Implementation of the WG-8 Permutation Module WGP-8 (x^{19})

The most complicated WGP-8 (x^{19}) module can be implemented using three different methods: a) a 256-byte direct look-up table; b) a 34-byte coset leader based lookup table; or c) tower field (TF) arithmetic.

Directly Look-up Table (DLT) Approach. Depending on the bases used, one can precompute the WG-8 permutation with decimation d = 19 by

$$\mathsf{WGP-8}(x^{19}) = q(x^{19} + 1) + 1$$

for all elements $x \in \mathbb{F}_{2^8}$. Hence, a 256-byte look-up table $T_{\mathsf{WGP-8}}$ can be generated to compute $\mathsf{WGP-8}(x^{19})$.

Coset Leader Based Look-up Table (CLT) Approach. This approach assumes that a normal basis is used to represent elements in \mathbb{F}_{2^8} and uses the essential property of the WG-8 permutation with decimation d below:

WGP-8
$$((x^{2^{i}})^{d}) = q((x^{2^{i}})^{d} + 1) + 1$$

= $q((x^{d})^{2^{i}} + 1) + 1 = (q(x^{d} + 1))^{2^{i}} + 1$
= $(q(x^{d} + 1) + 1)^{2^{i}} = (WGP-8(x^{d}))^{2^{i}}$ (1)

for $x \in \mathbb{F}_{2^8}$ and $i = 0, 1, \ldots, 7$. According to the Equation (1), if we know the WG-8 permutation WGP-8(x^d) for an element $x \in \mathbb{F}_{2^8}$, we can easily obtain the WG-8 permutation WGP-8 $((x^{2^i})^d)$ for the entire conset $\{x^2, x^{2^2}, \dots, x^{2^7}\}$ of x by cyclically shifting WGP-8 (x^d) to the right by *i* positions, provided that a normal basis is employed to represent finite field elements. The complete cosets and coset leaders of \mathbb{F}_{2^8} (in hexadecimal notation) are shown in Table 1. We note that under the normal basis representation the elements in \mathbb{F}_{2^8} have been grouped into 34 different cosets except for 0 and 1. Since WGP-8(0) = 0x00 and WGP-8(1) =0xFF, we only need to generate a 34-byte look-up table $T_{Co-WGP-8}$ for storing the WG-8 permutation results for each coset leader. Here we present the following Algorithm 1 that uses the table $T_{Co-WGP-8}$ to compute WGP-8(x^d) for any $x \in \mathbb{F}_{2^8}$.

Tower Field Arithmetic (TFA) Based Approach. The software implementation of the WGP-8 (x^{19}) module involves the arithmetic (i.e., addition, multiplication, and exponentiation) over finite field \mathbb{F}_{2^8} . Although we can directly implement all the operations over \mathbb{F}_{2^8} , it is well known that using the isomorphic tower constructions of \mathbb{F}_{2^8} might save the memory consumption. Therefore, we investigate the tower construction $\mathbb{F}_{(2^4)^2}$ in this work.

Tower Construction $\mathbb{F}_{(2^4)^2}$ and Its Arithmetic. To obtain the tower construction $\mathbb{F}_{(2^4)^2}$, we first construct \mathbb{F}_{2^4} by using an irreducible polynomial e(X) Algorithm 1 Coset Leader Based Look-up Table Approach

Input: $x \in F_{2^8}$, a decimation d, a look-up table $T_{\text{Co-WGP-8}}$

Output: WGP-8 (x^d)

- 1: if $x = 0 \times 00$ or $x = 0 \times FF$ then
- 2: return x
- 3: end if
- 4: Find the coset leader x_c of x by cyclically shifting x to the right by i positions, where $0 \le i \le 7$ (i.e., x_c is the smallest odd integer in the coset containing x.)
- 5: Find the position j of x_c in the table $T_{Co-WGP-8}$

6: $a \leftarrow T_{\text{Co-WGP-8}}[j]$

7: return $a \ll i$

of degree 4 over \mathbb{F}_2 , and then construct $\mathbb{F}_{(2^4)^2}$ by using a certain irreducible polynomial f(X) of degree 2 over \mathbb{F}_{2^4} . In our tower construction, we use $e(X) = X^4 + X^3 + 1$ with its polynomial basis $\{1, \alpha, \alpha^2, \alpha^3\}$ for \mathbb{F}_{2^4} and $f(X) = X^2 + X + \alpha$ with its normal basis $\{\beta, \beta^{16}\}$ for $\mathbb{F}_{(2^4)^2}$, where $\alpha = \omega^{119} \in \mathbb{F}_{2^4}$ and $\beta = \omega^7 \in \mathbb{F}_{(2^4)^2}$ are zeros of the polynomials e(X) and f(X), respectively.

Arithmetic operations in \mathbb{F}_{2^4} . The arithmetic in \mathbb{F}_{2^4} is conducted with the aid of a 4×4 exponentiation table T_{exp} and a 4×4 logarithm table T_{log} . While the table T_{exp} stores exponentiation $\alpha^i, i = 0, 1, \ldots, 14$, the table T_{log} keeps the exponent *i* for each $\alpha^i, i = 0, 1, \ldots, 14$. Let $A = a_0 + a_1\alpha + a_2\alpha^2 + a_3\alpha^3$ and $B = b_0 + b_1\alpha + b_2\alpha^2 + b_3\alpha^3$ be two non-zero elements in \mathbb{F}_{2^4} , where $a_i, b_i \in \mathbb{F}_2, i = 0, 1, 2, 3$. We can perform the arithmetic in \mathbb{F}_{2^4} as follows:

$$AB = T_{exp}[(T_{log}[(a_0, a_1, a_2, a_3)] + T_{log}[(b_0, b_1, b_2, b_3)]) \mod 15],$$

$$A^2 = T_{exp}[(T_{log}[(a_0, a_1, a_2, a_3)] \ll 1) \mod 15],$$

$$\alpha A = T_{exp}[(T_{log}[(a_0, a_1, a_2, a_3)] + 1) \mod 15].$$

Arithmetic operations in $\mathbb{F}_{(2^4)^2}$. Let $A = a_0\beta + a_1\beta^{16}$ and $B = b_0\beta + b_1\beta^{16}$, where $a_0, a_1, b_0, b_1 \in \mathbb{F}_{2^4}$. A multiplication AB in $\mathbb{F}_{(2^4)^2}$ is computed as follows:

$$AB = (a_0\beta + a_1\beta^{16})(b_0\beta + b_1\beta^{16})$$
$$= (c\alpha \oplus a_0b_0)\beta + (c\alpha \oplus a_1b_1)\beta^{16},$$

Table 1. The Cosets and Coset Leaders of \mathbb{F}_{2^8}

where $c = (a_0 \oplus a_1)(b_0 \oplus b_1)$. For a non-zero element $A \in \mathbb{F}_{(2^4)^2}$, the squaring of A is calculated as follows:

$$A^{2} = (a_{0}\beta + a_{1}\beta^{16})^{2}$$

= $[(a_{0} \oplus a_{1})^{2}\alpha \oplus a_{0}^{2}]\beta + [(a_{0} \oplus a_{1})^{2}\alpha \oplus a_{1}^{2}]\beta^{16}.$

The Frobenius mapping of A with respect to \mathbb{F}_{2^4} , which is the 16th power operation, is computed as follows:

$$A^{2^4} = (a_0\beta + a_1\beta^{16})^{16} = a_0\beta^{16} + a_1\beta^{256} = a_1\beta + a_0\beta^{16}.$$

Implementation of WGP-8 (x^{19}) Module. For an element $x \in \mathbb{F}_{2^8}$, the WGP-8 (x^{19}) can be computed as follows:

$$\begin{split} \mathsf{WGP-8}(x^{19}) &= q(x^{19}+1)+1 \\ &= y+y^{2^3+1}+y^{2^6}(y^{2^3+1}+y^{2^3-1})+y^{2^3(2^3-1)+1}+1, \end{split}$$

where $y = x^{19} + 1 = x^{2^4} \cdot x^2 \cdot x + 1$. Note that for the tower construction $\mathbb{F}_{(2^4)^2}$, 1 can be denoted by the vector (1, 0, 0, 0, 1, 0, 0, 0). Therefore, the addition with 1 under the TF representation is equivalent to XORing with a constant 0x88.

4.2. Implementation of the Trace Computation Module $\mathrm{Tr}(\cdot)$

Depending on the bases chosen, the trace of an element $x \in \mathbb{F}_{2^8}$ can be computed as shown in Table 2.

4.3. Implementation of the Multiplication by ω Module

The multiplication by ω module can be implemented using either finite field arithmetic or an 8×8 look-up table.

Multiplication by ω Using Finite Field Arithmetic. We consider the following three cases when the PB, NB, and TF are used to represent finite field elements, respectively. With the PB representation, the multiplication of an element $x \in \mathbb{F}_{2^8}$ by ω can be computed as follows:

$$x \cdot \omega = x_0 \omega + x_1 \omega^2 + \dots + x_6 \omega^7 + x_7 \omega^8$$

= $x_7 + x_0 \omega + (x_1 \oplus x_7) \omega^2 + (x_2 \oplus x_7) \omega^3 + (x_3 \oplus x_7) \omega^4 + x_4 \omega^5 + x_5 \omega^6 + x_6 \omega^7.$ (2)

Therefore, the result of $x \cdot \omega$ is represented as an 8-bit vector $(x_7, x_0, x_1 \oplus x_7, x_2 \oplus x_7, x_3 \oplus x_7, x_4, x_5, x_6)$ with respect the PB.

Basis	Element Representation	$\operatorname{Tr}(x)$
Polynomial Basis (PB)	$x_0 + x_1\omega + \dots + x_7\omega^7$	x_5
Normal Basis (NB)	$x_0\theta + x_1\theta^2 + \dots + x_7\theta^{2^7}$	$\bigoplus_{i=0}^7 x_i$
Tower Field (TF)	$\frac{(x_0 + x_1\alpha + x_2\alpha^2 + x_3\alpha^3)\beta +}{(x_4 + x_5\alpha + x_6\alpha^2 + x_7\alpha^3)\beta^{16}}$	$x_1 \oplus x_2 \oplus x_3 \oplus x_5 \oplus x_6 \oplus x_7$

Table 2. Trace Computation of an Element $x \in \mathbb{F}_{2^8}$ Using Different Bases

With the NB representation, the multiplication of an element $x \in \mathbb{F}_{2^8}$ by ω can be calculated as follows:

$$x \cdot \omega = (x_0\theta + x_1\theta^2 + \dots + x_6\theta^{2^6} + x_7\theta^{2^7}) \cdot \omega$$
$$= \mathbf{M} \cdot (x_0, x_1, \dots, x_6, x_7)^T, \qquad (3)$$

where the matrix \mathbf{M} is given below:

	$\begin{pmatrix} 1 \end{pmatrix}$	1	1	0	1	0	1	1	
	0	0	0	0	1	1	1	0	
	1	0	1	0	1	0	0	1	
Ν/Г —	1	0	1	1	1	0	0	0	
$\mathbf{W} =$	0	0	1	0	1	1	1	0	•
	0	1	1	0	0	1	1	1	
	1	0	1	1	1	1	0	0	
	0	1	1	0	1	0	1	1)	

With the TF representation, the multiplication of an element $x \in \mathbb{F}_{2^8}$ by ω can be calculated as follows:

$$x \cdot \omega = [(x_0 + x_1 \alpha + x_2 \alpha^2 + x_3 \alpha^3)\beta + (x_4 + x_5 \alpha + x_6 \alpha^2 + x_7 \alpha^3)\beta^{16}] \cdot \omega$$
$$= \mathbf{M}' \cdot (x_0, x_1, \cdots, x_6, x_7)^T, \tag{4}$$

where the matrix \mathbf{M}' is given below:

Multiplication by ω **Using Look-Up Tables.** Based on the Equations (2)–(4), one can generate 256-byte look-up tables with respect to the chosen bases.

4.4. Implementation Platforms and Development Tools

In this section, we briefly describe two low-power microcontrollers for implementing the WG-8 stream cipher as well as the corresponding development tools.

8-Bit Microcontroller ATmega128L and Development Tool. The low-power 8-bit microcontroller ATmega128L [1] from Atmel is based on the AVR enhanced RISC architecture with 128 Kbytes of In-System Self-Programmable Flash, 4 Kbytes EEPROM and 8 Kbytes Internal SRAM. It is equipped with 133 highly-optimized instructions and most of them can be executed within one clock cycle. Moreover, the clock frequency of the ATmega128L can run from 0 to 8 MHz and the power supplies can go from 2.7 to 5.5 V. We use the latest integrated development environment Atmel Studio 6.0 [2] from Atmel for implementing and testing the performance of the WG-8 on the target platform.

16-Bit Microcontroller MSP430F1611 and Development Tool. The 16-bit microcontroller MSP430F1611 [40] from Texas Instruments has a traditional von-Neumann architecture with 48 Kbytes Flash memory and 10 Kbytes RAM. All special function registers, peripherals, RAM and Flash/ROM share the same address space. The clock frequency of the MSP430F1611 ranges from 0 to 8 MHz and the power supplies can go from 1.8 to 3.6 V. The MSP430F1611 features 27 instructions and 7 different addressing modes that provide great flexibility in data manipulation. To implement and simulate the WG-8 on the target platform, we use the CrossWorks for MSP430 Version 2.1 from Rowley Associates [37].

4.5. Experimental Results and Comparisons

In this section, we report our experimental results for implementing the stream cipher WG-8 on the low-power microcontrollers ATmega128L and MSP430F1611 and compare our results with other lightweight-cryptography implementations on the same or similar platforms. We focus on three major performance criteria for implementing cryptographic primitives on resource-constrained environments, namely throughput, code size, and energy consumption (i.e., energy/bit). Table 3 compares our implementation results with previous work in terms of the aforementioned three performance criteria. Note that we estimate the per bit energy consumptions by the formula: $energy/bit = \frac{Supply Voltage \times Current \times Cycles}{Clock Frequency \times Number of Bits}$ which is based on the typical current consumption of a low-power microcontroller for the given clock frequency and supply voltage.

From Table 3, we note that on 8-bit ATmega microcontrollers the throughput of WG-8 is about $2 \sim 15$ times higher than that of stream ciphers Grain, Trivium, Salsa20, and WG-7, block ciphers PRESENT-80 and XTEA as well as the hybrid cipher Hummingbird, whereas the energy consumption of WG-8 is around $2 \sim 220$ times smaller than that of those ciphers. Moreover, WG-8 has the comparable throughput and energy efficiency with the hybrid cipher Hummingbird-2 (optimized with assembly language). On the 8-bit platform, WG-8 is less efficient than AES in terms of throughput and energy consumption. The main reason is that WG-8 is a bitoriented stream cipher whereas AES is a block cipher with block size 128-bit. Furthermore, the code size of WG-8 is medium and the SRAM usage of WG-8 is small among all the lightweight implementations.

On 16-bit MSP430 microcontrollers, the throughput of WG-8 is about $1 \sim 20$ times higher than that of the stream cipher WG-7 as well as block ciphers PRINTcipher-48, AES, PRESENT-80, and KLEIN-64, whereas the energy efficiency is comparable with that of those ciphers. While WG-8 has similar throughput and energy efficiency as the hybrid cipher Hummingbird, it is less efficient when compared to the Hummingbird-2 cipher. The main reason comes from the optimization with the assembly language in the speed-optimized Hummingbird-2 implementation. Furthermore, the code size of WG-8 is about $2 \sim 7$ times smaller than block ciphers PRINTcipher-48, AES, PRESENT-80, and KLEIN-64 as well as the hybrid cipher Hummingbird-2, and is comparable with the Hummingbird cipher. Regarding to the SRAM usage, the stream cipher WG-8 is superior to other block cipher and stream ciphers.

In addition, for the three implementation variants, we note that on both 8-bit and 16-bit platforms the DLT method is consistently better than both CLT and TFA methods with respect to throughput and energy consumption. The reason lies in the efficient memory access for look-up tables on both microcontrollers.

5. Efficient Hardware Implementation of the Stream Cipher WG-8

Efficient hardware implementation of the WG-8 stream cipher on both FPGA and ASIC platforms has been extensively investigated in [42]. One look-up table based and three tower field based hardware architectures were proposed and compared to each other in terms of throughput, area, and power consumption. The experimental results show that a direct look-up table based hardware architecture can achieve a maximum throughput of 190 Mbps (resp. 500 Mbps) and require 137 slices (resp. 1786 Gate Equivalents (GEs)) on a Xilinx Spartan-3 FPGA (resp. 65nm CMOS ASIC) platform, at the cost of the dynamic power consumption of 0.005 W (resp. 0.983 mW). Moreover, the look-up table based method is optimal with respect to the defined performance metrics when compared to the tower field based approaches. For certain performance metrics, the WG-8 hardware core compares well with the lightweight stream ciphers Grain [22], Trivium [7], and MICKEY [3].

6. Conclusion

In this paper, we present a lightweight stream cipher WG-8 targeted for resource-constrained devices like RFID tags, smart cards, and wireless sensor nodes, which inherits all the good randomness and cryptographic properties of the well-known WG stream cipher family. A detailed cryptanalysis shows that WG-8 is resistant to the most common attacks against stream ciphers. Moreover, the software implementations on low-power microcontrollers demonstrate the high performance and
